

Locality weighted distribution

🕒 2 minute read ✓ page test

Follow this guide to configure the distribution of traffic across localities.

Before proceeding, be sure to complete the steps under before you begin.

In this task, you will use the `sleep pod` in `region1 zone1` as the source of requests to the `HelloWorld` service. You will configure Istio with the following distribution across localities:

Region	Zone	% of traffic
region1	zone1	70
region1	zone2	20
region2	zone3	0
region3	zone4	10

Configure Weighted Distribution

Apply a `DestinationRule` that configures the following:

- Outlier detection for the `HelloWorld` service. This is required in order for distribution to function properly. In particular, it configures the sidecar proxies to know when endpoints for a service are unhealthy.

- **Weighted Distribution for the HelloWorld service as described in the table above.**

```
$ kubectl --context="${CTX_PRIMARY}" apply -n sample -f - <<EOF
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: helloworld
spec:
  host: helloworld.sample.svc.cluster.local
  trafficPolicy:
    loadBalancer:
      localityLbSetting:
        enabled: true
        distribute:
          - from: region1/zone1/*
            to:
              "region1/zone1/*": 70
              "region1/zone2/*": 20
EOF
```

```
"region3/zone4/*": 10
```

```
outlierDetection:
```

```
  consecutive5xxErrors: 100
```

```
  interval: 1s
```

```
  baseEjectionTime: 1m
```

```
EOF
```

Verify the distribution

Call the `HelloWorld` service from the `Sleep` pod:

```
$ kubectl exec --context="${CTX_R1_Z1}" -n sample -c sleep \
  "$ (kubectl get pod --context="${CTX_R1_Z1}" -n sample -l \
    app=sleep -o jsonpath='{.items[0].metadata.name}')" \
  -- curl -sSL helloworld.sample:5000/hello
```

Repeat this a number of times and verify that the number of replies for each pod match the expected percentage in the table at the top of this guide.

Congratulations! You successfully configured locality distribution!
